

LAMBDA EXPRESSION

What is Lambda expression

- **Lambda expressions in Java**, introduced in Java SE 8, represent instances of functional interfaces (interfaces with a single abstract method). They provide a concise way to express instances of single-method interfaces using a block of code.
- It saves a lot of code. In the case of the lambda expression, we don't need to define the method again for providing the implementation.

Java Lambda Expression Syntax

- Java Lambda Expression Syntax

```
(argument-list) -> {body}
```

- Java lambda expression consists of the following three components:

1.Argument-list : It can be empty or non-empty as well.

2.Arrow-token : It is used to link the arguments list and body of expression.

3.Body : It contains expressions and statements for lambda expression.

Example of functional interface by using the anonymous class

```
package yearTwo;  
@FunctionalInterface  
public interface Printer {  
    abstract void print();  
}
```

```
package yearTwo;  
  
public class PrinterMain {  
    public static void main(String[] args) {  
        Printer p=new Printer() {  
            @Override  
            public void print() {  
                System.out.println("the implemetation of the interface by using anonymous class");  
            }  
        };  
        p.print();  
    }  
}
```

Example of functional interface by using lambda expression

```
package year1two;

public class PrinterMain {

    public static void main(String[] args) {
        // TODO Auto-generated method stub
        Printer p=()->System.out.println("here is the implementation of functional interface");
        p.print();
    }

}
```
